

The maximum absolute value of the meridional stress in the isogrid “layer” in the STAGS model is  $32.2 \times 5440 = 175168$  psi, which significantly exceeds the absolute value of STFMXS in shell segment 1 in Table 43: STFMXS = 122550 psi. The discrepancy arises because the STAGS model treats the isogrid “layer” as an isotropic layer in which the isogrid is “smeared”, whereas in the BIGBOSOR4 model (Table 43) the extreme fiber meridional stress in the isogrid “layer” is computed for a single isogrid stiffener member oriented in the meridional coordinate direction (Eqs.7-9). Therefore, at the pole the STAGS prediction for perfect agreement with the BIGBOSOR4 prediction would have to be  $[1/(1-\nu)] \times (122550) = 183825$  psi, in which  $\nu$ =Poisson ratio = 1/3 for an isogrid configuration. NOTE: The BIGBOSOR4 prediction, listed in Table 43 for the +mode 2 imperfection, only gives the maximum value of the extreme fiber meridional stress in each shell segment, not both the maximum **inner** fiber meridional stress and maximum **outer** fiber meridional stress.

Fig. 24 STAGS prediction of the **inner fiber meridional stress sigma1 (psi) in the isogrid “layer”** of the optimized **+mode 2 imperfect isogrid-stiffened** equivalent ellipsoidal shell subjected to the external design pressure,  $p = 460$  psi. Compare with STFMXS in Table 43. Consider the effect of Eqs.(7-9) in making the comparison!
