

Fig. 250 **Optimized unstiffened equivalent ellipsoidal shell with thick apex, $t(\text{apex})=0.61996$ inch; $W_{\text{imp}}=0.2$ inch; this figure pertains to the shell design listed in Table 93.** Shown here are the load cycles for load set B (load factor PB) that produce a residual “ $\cos(\theta)$ ” dent of depth just above 0.2 inch. Compare with Fig. 245. These results correspond to what is called **Case 3** in Fig. 232: the “ $\cos(\theta)$ ” line load is applied along Row 4 of Shell Segment 7 from circumferential coordinate, $\theta = 0$ to 90 degrees. This load distribution is used because it generates a residual dent that **locally** resembles the negative of the deformation in Figs. 232 and 233, that is, the negative of the linear buckling modal imperfection with $n = 1$ circumferential wave.
